

SQL - Lab Assignment #1

Introduction

In this lesson, we'll run through some practice questions to reinforce your knowledge of SQL queries.

Objectives

You will be able to:

- Practice interpreting "word problems" and translating them into SQL queries
- Practice deciding and performing whichever type of `JOIN` is best for retrieving desired data
- Practice using `GROUP BY` statements in SQL to apply aggregate functions like `COUNT` , `MAX` , `MIN` , and `SUM`
- Practice using the `HAVING` clause to compare different aggregates
- Practice writing subqueries to decompose complex queries

Your Task: Querying a Customer Database

 shelves filled with colorful model cars

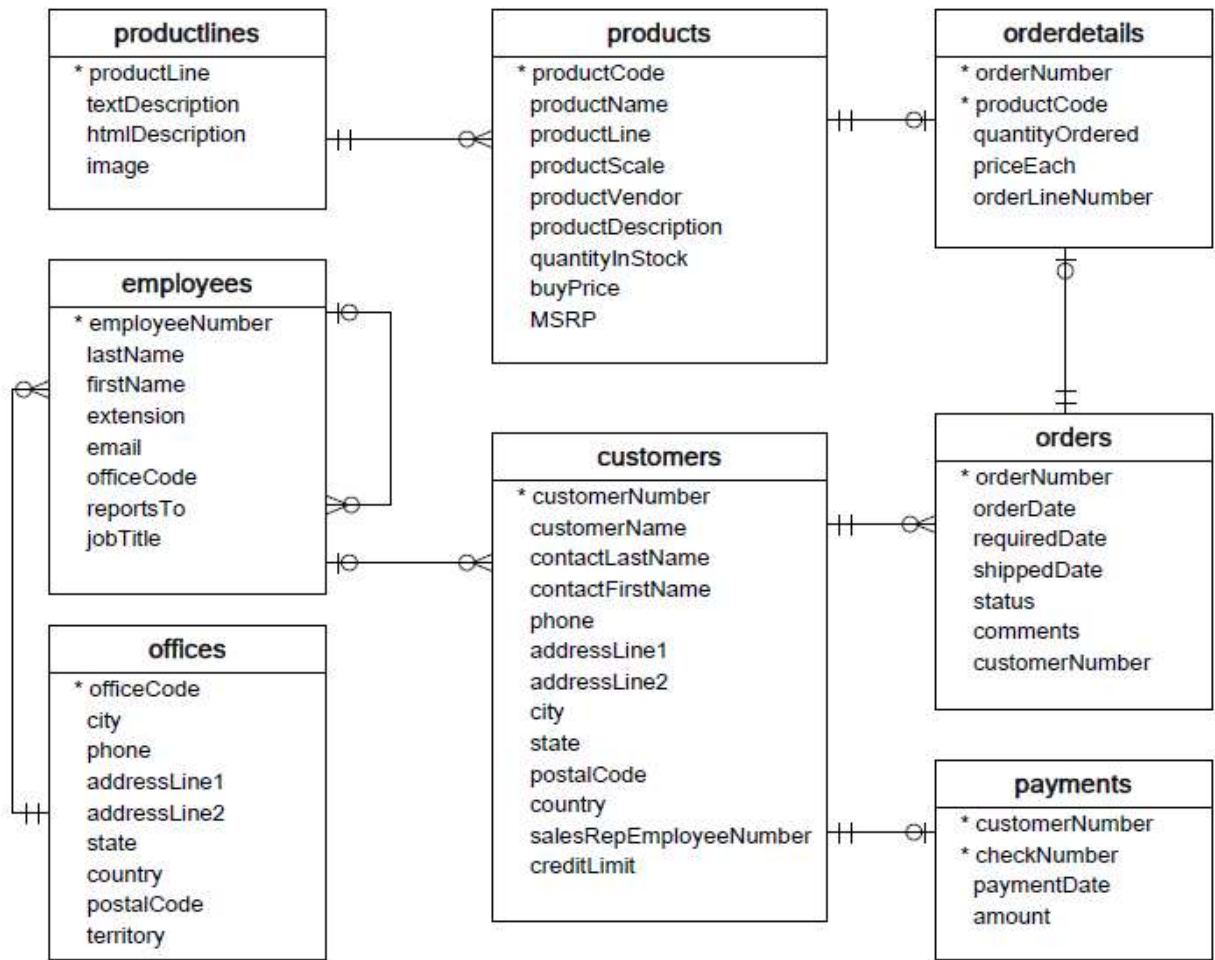

Photo by [Karen Vardazaryan \(https://unsplash.com/@bright?utm_source=unsplash&utm_medium=referral&utm_content=creditCopyText\)](https://unsplash.com/@bright?utm_source=unsplash&utm_medium=referral&utm_content=creditCopyText) on [Unsplash \(https://unsplash.com/photos/model-car?utm_source=unsplash&utm_medium=referral&utm_content=creditCopyText\)](https://unsplash.com/photos/model-car?utm_source=unsplash&utm_medium=referral&utm_content=creditCopyText)

Business Understanding

Your employer makes miniature models of products such as classic cars, motorcycles, and planes. They want you to pull several reports on different segments of their past customers, in order to better understand past sales as well as determine which customers will receive promotional material.

Data Understanding

You may remember this database from a previous lab. As a refresher, here's the ERD diagram for this database:

The queries you are asked to write will become more complex over the course of the lab.

Getting Started

As in previous labs, we'll make use of the `sqlite3` library as well as `pandas`. By combining them, we'll be able to write queries as Python strings, then display the results in a conveniently-formatted table.

Note: Throughout this lesson, the only thing you will need to change is the content of the strings containing SQL queries. You do NOT need to modify any of the code relating to `pandas`; this is just to help make the output more readable.

In the cell below, we:

- Import the necessary libraries, `pandas` and `sqlite3`
- Establish a connection to the database `data.sqlite`, called `conn`

```
In [9]: ➤ import pandas as pd
```

```
In [10]:  ► %%capture
!pip install ipython-sql sqlalchemy
import sqlalchemy
engine=sqlalchemy.create_engine("sqlite:///data.sqlite")
%load_ext sql
%sql sqlite:///data.sqlite
```

The basic structure of a query in this lab is:

- Write the SQL query inside of the Python string
- Use `pd.read_sql` to display the results of the query in a formatted table

For example, if we wanted to select a list of all product lines from the company, that would look like this:

```
In [11]:  ► from sqlalchemy import inspect
insp=inspect(engine)
insp.get_table_names()
```

```
Out[11]: ['customers',
          'employees',
          'offices',
          'orderdetails',
          'orders',
          'payments',
          'productlines',
          'products']
```

From now on, you will replace `None` within these Python strings with the actual SQL query code.

Part 1: Basic Queries

First, let's review some basic SQL queries, which do not require any joining, aggregation, or subqueries.

Query 1: Customers with Credit Over 25,000 in California

Write a query that gets the contact first name, contact last name, phone number, address line 1, and credit limit for all customers in California with a credit limit greater than 25000.00.

(California means that the `state` value is `'CA'`.)

Expected Output

```
In [12]: q1= f"""
SELECT contactFirstName, contactLastName,phone,addressLine1,creditLimit
From customers
Where creditLimit>25000 and state='CA'
"""

q1_result=pd.read_sql(q1,engine)
q1_result
```

Out[12]:

	contactFirstName	contactLastName	phone	addressLine1	creditLimit
0	Susan	Nelson	4155551450	5677 Strong St.	210500
1	Julie	Murphy	6505555787	5557 North Pendale Street	64600
2	Juri	Hashimoto	6505556809	9408 Furth Circle	84600
3	Julie	Young	6265557265	78934 Hillside Dr.	90700
4	Valarie	Thompson	7605558146	361 Furth Circle	105000
5	Julie	Brown	6505551386	7734 Strong St.	105000
6	Brian	Chandler	2155554369	6047 Douglas Av.	57700
7	Sue	Frick	4085553659	3086 Ingle Ln.	77600
8	Steve	Thompson	3105553722	3675 Furth Circle	55400
9	Sue	Taylor	4155554312	2793 Furth Circle	60300

The following code checks that your result is correct:

```
In [13]: # Run this cell without changes

# Testing which columns are returned
assert list(q1_result.columns) == ['contactFirstName', 'contactLastName', 'ph

# Testing how many rows are returned
assert len(q1_result) == 10

# Testing the values in the first result
assert list(q1_result.iloc[0]) == ['Susan', 'Nelson', '4155551450', '5677 Str
```

Query 2: Customers Outside of the USA with "Collect" in Their Name

Write a query that gets the customer name, state, and country, for all customers outside of the USA with "Collect" as part of their customer name.

We are looking for customers with names like "Australian Collectors, Co." or "BG&E Collectables", where country is not "USA".

Expected Output

In [14]:

%%sql

```
SELECT * FROM customers
limit 1
```

```
* sqlite:///data.sqlite
```

Done.

Out[14]:

customerNumber	customerName	contactLastName	contactFirstName	phone	addressLine1
103	Atelier graphique	Schmitt	Carine	40.32.2555	54, rue Royale

In [15]:

Replace None with appropriate SQL code

```
q2 = """
SELECT customerName,state, country
FROM customers
where country!= "USA" and customerName like "%Collect%"
;
"""
```

```
q2_result = pd.read_sql(q2, engine)
q2_result
```

Out[15]:

	customerName	state	country
0	Australian Collectors, Co.	Victoria	Australia
1	Clover Collections, Co.	None	Ireland
2	UK Collectables, Ltd.	None	UK
3	King Kong Collectables, Co.	None	Hong Kong
4	Heintze Collectables	None	Denmark
5	Royal Canadian Collectables, Ltd.	BC	Canada
6	BG&E Collectables	None	Switzerland
7	Reims Collectables	None	France
8	Precious Collectables	None	Switzerland
9	Salzburg Collectables	None	Austria
10	Tokyo Collectables, Ltd	Tokyo	Japan
11	Stuttgart Collectable Exchange	None	Germany
12	Bavarian Collectables Imports, Co.	None	Germany
13	Australian Collectables, Ltd	Victoria	Australia
14	Kremlin Collectables, Co.	None	Russia

The following code checks that your result is correct:

```
In [16]: ▶ # Run this cell without changes

# Testing which columns are returned
assert list(q2_result.columns) == ['customerName', 'state', 'country']

# Testing how many rows are returned
assert len(q2_result) == 15

# Testing the values in the first result
assert list(q2_result.iloc[0]) == ['Australian Collectors, Co.', 'Victoria',
```

Query 3: Customers without Null States

Write a query that gets the full address (line 1, line 2, city, state, postal code, country) for all customers where the `state` field is not null.

Here we'll only display the first 10 results.

Expected Output

```
In [17]: ▶ # Replace None with appropriate SQL code
q3 = """
SELECT addressLine1, addressLine2, city, state, postalCode, country
FROM customers
where "state" IS NOT NULL
;
"""

q3_result = pd.read_sql(q3, engine)
q3_result.head(10)
```

Out[17]:

	addressLine1	addressLine2	city	state	postalCode	country
0	8489 Strong St.		Las Vegas	NV	83030	USA
1	636 St Kilda Road	Level 3	Melbourne	Victoria	3004	Australia
2	5677 Strong St.		San Rafael	CA	97562	USA
3	5557 North Pendale Street		San Francisco	CA	94217	USA
4	897 Long Airport Avenue		NYC	NY	10022	USA
5	4092 Furth Circle	Suite 400	NYC	NY	10022	USA
6	7586 Pompton St.		Allentown	PA	70267	USA
7	9408 Furth Circle		Burlingame	CA	94217	USA
8	149 Spinnaker Dr.	Suite 101	New Haven	CT	97823	USA
9	4658 Baden Av.		Cambridge	MA	51247	USA

The following code checks that your result is correct:

```
In [18]: ▶ # Run this cell without changes

# Testing which columns are returned
assert list(q3_result.columns) == ['addressLine1', 'addressLine2', 'city', 's

# Testing how many rows are returned
assert len(q3_result) == 49

# Testing the values in the first result
assert list(q3_result.iloc[0]) == ['8489 Strong St.', '', 'Las Vegas', 'NV',
```

You have now completed all of the basic queries!

Part 2: Aggregate and Join Queries

Query 4: Average Credit Limit by State in USA

Write a query that gets the average credit limit per state in the USA.

The two fields selected should be `state` and `average_credit_limit`, which is the average of the `creditLimit` field for that state.

Expected Output

```
In [19]: # Replace None with appropriate SQL code
q4 = """
SELECT state,AVG(creditLimit) as average_credit_limit
FROM customers
WHERE country =='USA'
GROUP BY "state"
;
"""

q4_result = pd.read_sql(q4, engine)
q4_result
```

Out[19]:

	state	average_credit_limit
0	CA	83854.545455
1	CT	57350.000000
2	MA	70755.555556
3	NH	114200.000000
4	NJ	43000.000000
5	NV	71800.000000
6	NY	89966.666667
7	PA	84766.666667

The following code checks that your result is correct:

```
In [20]: # Run this cell without changes

# Testing which columns are returned
assert list(q4_result.columns) == ['state', 'average_credit_limit']

# Testing how many rows are returned
assert len(q4_result) == 8

# Testing the values in the first result
first_result_list = list(q4_result.iloc[0])
assert first_result_list[0] == 'CA'
assert round(first_result_list[1], 3) == round(83854.54545454546, 3)
```

Query 5: Joining Customers and Orders

Write a query that uses `JOIN` statements to get the customer name, order number, and status for all orders. Refer to the ERD above to understand which tables contain these pieces of information, and the relationship between these tables.

We will only display the first 15 results.

Expected Output

In [21]:  %%sql

```
SELECT * FROM orders
limit 2
```

* sqlite:///data.sqlite

Done.

Out[21]:

orderNumber	orderDate	requiredDate	shippedDate	status	comments	customerNumber
10100	2003-01-06	2003-01-13	2003-01-10	Shipped		363
10101	2003-01-09	2003-01-18	2003-01-11	Shipped	Check on availability.	128

In [22]:  %%sql

```
SELECT * FROM customers
limit 2
```

* sqlite:///data.sqlite

Done.

Out[22]:

customerNumber	customerName	contactLastName	contactFirstName	phone	addressLine1
103	Atelier graphique	Schmitt	Carine	40.32.2555	54, rue Roya
112	Signal Gift Stores	King	Jean	7025551838	8489 Stror S

In [23]:  %%sql

* sqlite:///data.sqlite

```
In [24]: # Replace None with appropriate SQL code
q5 = """
SELECT c.customerName, o.orderNumber, o.status
FROM customers as c
INNER JOIN orders as o
on c.customerNumber=o.customerNumber
;
"""
q5_result = pd.read_sql(q5, conn)
q5_result.head(15)
```

```
-----
NameError                                Traceback (most recent call last)
Input In [24], in <cell line: 9>()
      1 # Replace None with appropriate SQL code
      2 q5 = """
      3 SELECT c.customerName, o.orderNumber, o.status
      4 FROM customers as c
      5 (...)
      6 ;
      7 """
----> 9 q5_result = pd.read_sql(q5, conn)
     10 q5_result.head(15)

NameError: name 'conn' is not defined
```

The following code checks that your result is correct:

```
In [ ]: # Run this cell without changes

# Testing which columns are returned
assert list(q5_result.columns) == ['customerName', 'orderNumber', 'status']

# Testing how many rows are returned
assert len(q5_result) == 326

# Testing the values in the first result
assert list(q5_result.iloc[0]) == ['Atelier graphique', 10123, 'Shipped']
```

Query 6: Total Payments

Write a query that uses `JOIN` statements to get top 10 customers in terms of total payment amount. Find the customer name, customer number, and sum of all payments made. The results should be ordered by the sum of payments made, starting from the highest value.

The three columns selected should be `customerName`, `customerNumber` and `total_payment_amount`.

Expected Output

	customerName	customerNumber	total_payment_amount
0	Euro+ Shopping Channel	141	715738.98
1	Mini Gifts Distributors Ltd.	124	584188.24
2	Australian Collectors, Co.	114	180585.07
3	Muscle Machine Inc	151	177913.95
4	Dragon Souvenirs, Ltd.	148	156251.03
5	Down Under Souvenirs, Inc	323	154622.08
6	AV Stores, Co.	187	148410.09
7	Anna's Decorations, Ltd	276	137034.22
8	Corporate Gift Ideas Co.	321	132340.78
9	Saveley & Henriot, Co.	146	130305.35

In []: `%%sql`

```
SELECT * FROM payments
limit 1
```

In []: `# Replace None with appropriate SQL code`

```
q6 = """
SELECT c.customerName, c.customerNumber,SUM(p.amount) as total_payment_amount
FROM customers as c
INNER JOIN payments as p
on c.customerNumber=p.customerNumber
GROUP BY c.customerNumber
ORDER BY total_payment_amount DESC
limit 10
;
"""

q6_result = pd.read_sql(q6, engine)
q6_result
```

The following code checks that your result is correct:

In []: `# Run this cell without changes`

```
# Testing which columns are returned
assert list(q6_result.columns) == ['customerName', 'customerNumber', 'total_p

# Testing how many rows are returned
assert len(q6_result) == 10

# Testing the values in the first result
assert list(q6_result.iloc[0]) == ['Euro+ Shopping Channel', 141, 715738.98]
```

Query 7: Products that Have Been Purchased 10 or More Times

Write a query that, for each customer, finds all of the products that they have purchased 10 or more times cumulatively. For each record, return the customer name, customer number, product name, product code, and total number ordered. Sort the rows in descending order by the quantity ordered.

The five columns selected should be `customerName` , `customerNumber` , `productName` , `productCode` , and `total_ordered` , where `total_ordered` is the sum of all quantities of that product ordered by that customer.

Hint: For this one, you'll need to make use of `HAVING` , `GROUP BY` , and `ORDER BY` — make sure you get the order of them correct!

Expected Output

```
In [96]: ##CusomerOrder

q7="""
SELECT c.customerName,c.customerNumber,p.productName,od.productCode,SUM(od.qu
FROM customers as c
JOIN orders as o on c.customerNumber=o.customerNumber
JOIN orderdetails as od on o.orderNumber=od.orderNumber
JOIN products as p on p.productCode=od.productCode
GROUP BY c.customerName,p.productName
HAVING total_ordered>=10
ORDER BY total_ordered
;
"""

q7_result=pd.read_sql(q7,engine)
q7_result
```

Out[96]:

	customerName	customerNumber	productName	productCode	total_ordered
0	Extreme Desk Decorations, Ltd	412	1961 Chevrolet Impala	S24_4620	10
1	Petit Auto	314	1913 Ford Model T Speedster	S18_2949	10
2	La Rochelle Gifts	119	1954 Greyhound Scenicruiser	S32_2509	11
3	Tekni Collectables Inc.	328	American Airlines: B767-300	S700_1691	11
4	The Sharp Gifts Warehouse	450	1969 Chevrolet Camaro Z28	S24_3191	13
...
2526	Euro+ Shopping Channel	141	2002 Chevy Corvette	S24_3432	174
2527	Euro+ Shopping Channel	141	1957 Chevy Pickup	S12_4473	183

2529	Euro+ Shopping Channel	141	1958 Chevy Corvette Limited Edition	S24_2840	245
2530	Euro+ Shopping Channel	141	1992 Ferrari 360 Spider red	S18_3232	308

2531 rows × 5 columns

The following code checks that your result is correct:

```
In [97]: ▶ l without changes  
  
h columns are returned  
_result.columns) == ['customerName', 'customerNumber', 'productName', 'produc  
  
many rows are returned  
_result) == 2531  
  
values in the first result  
_result.iloc[0]) == ['Extreme Desk Decorations, Ltd', 412, '1961 Chevrolet Im
```

Query 8: Employees in Offices with Fewer than Five Employees

Finally, get the first name, last name, employee number, and office code for employees from offices with fewer than 5 employees.

Hint: Use a subquery to find the relevant offices.

Expected Output

```
In [230]: q8 = """
WITH total_employees AS (
    SELECT
        officeCode,count(officeCode) as total
    FROM
        employees
    GROUP BY
        officeCode
)
SELECT
    e.lastName,e.firstName,e.employeeNumber,et.officeCode
FROM
    employees AS e
    LEFT JOIN total_employees AS et
        ON e.officeCode = et.officeCode
Where et.total<5
;
"""
q8_result = pd.read_sql(q8, engine)
q8_result
```

Out[230]:

	lastName	firstName	employeeNumber	officeCode
0	Patterson	William	1088	6
1	Firrelli	Julie	1188	2
2	Patterson	Steve	1216	2
3	Tseng	Foon Yue	1286	3
4	Vanauf	George	1323	3
5	Bott	Larry	1501	7
6	Jones	Barry	1504	7
7	Fixter	Andy	1611	6
8	Marsh	Peter	1612	6
9	King	Tom	1619	6
10	Nishi	Mami	1621	5
11	Kato	Yoshimi	1625	5

The following code checks that your result is correct:

```
In [231]: ▶ # Run this cell without changes

# Testing which columns are returned
assert list(q8_result.columns) == ['lastName', 'firstName', 'employeeNumber',

# Testing how many rows are returned
assert len(q8_result) == 12

# Testing the values in the first result
assert list(q8_result.iloc[0]) == ['Patterson', 'William', 1088, 6]
```

Now that we are finished writing queries, close the connection to the database:

Summary

In this lesson, we produced several data queries for a model car company, mainly focused around its customer data. Along the way, we reviewed many of the major concepts and keywords associated with SQL SELECT queries: FROM , WHERE , GROUP BY , HAVING , ORDER BY , JOIN , SUM , COUNT , and AVG .
